SIDC Weekly bulletin on Solar and Geomagnetic activity
WEEK 472 from 2010 Jan 11

SOLAR ACTIVITY

Solar activity was low to moderately active with the transit of NOAA AR 1040, which was about 20 degrees east of the central meridian on Jan. 11th. It produced 3 C-flares during the week.

GEOMAGNETIC ACTIVITY

Geomagnetic activity was extremely low during the whole week.

SIDC Weekly bulletin on Solar and Geomagnetic activity
WEEK 473 from 2010 Jan 18

SOLAR ACTIVITY

The week started with NOAA AR 11040 disappearing over the west limb, on January 18.

On January 19, NOAA AR 11041 (ex NOAA AR 11039, Catania number 37, Beta magnetic configuration) rotated onto the visible solar disk and created the largest peak in solar activity in 2 years. It produced 6 M-class flares in 48 hours, the largest one was an M3.4 flare with peak at 17:55 UT on January 20, location S24E88. From January 21 onwards, solar activity decayed and no more M-class flares were seen. On January 22, a sunspot group with Catania number 38 (Beta magnetic configuration, it was given NOAA number 11042 on January 23) emerged at N21W19, but it did not produce any significant activity.

GEOMAGNETIC ACTIVITY

There was a minor geomagnetic storm during one 3-hour period (Kp=5) starting at 15:00 UT on January 20, caused by the late arrival of the fast solar wind from a coronal hole. No more disturbances were recorded.

SIDC Weekly bulletin on Solar and Geomagnetic activity
WEEK 474 from 2010 Jan 25

SOLAR ACTIVITY

Three sunspot groups were recorded on the solar disk during the week: Catania numbers 37, 38 and 39 (NOAA ARs 1041, 1042 and 1043 respectively). Catania sunspot group 38 was active in the beginning of the week. It produced several B-class flares on January 26-27, the strongest one being the B6.7 flare on January 26. Late on January 27 it disappeared behind the west limb. Catania sunspot group 37 produced several B-class flares on January 27-28, the strongest one being the B4.0 flare on January 28. Catania sunspot group 39 emerged rapidly on January 30 and produced several B-class flares on January 30-31, including the B4.8 flare on January 31.

GEOMAGNETIC ACTIVITY

During the most of the week, the Earth was inside a slow solar wind stream (speed below 400 km/s). The geomagnetic conditions were quiet. On January 30-31 a slightly faster solar wind stream arrived (peak speed μ

around 450 km/s), accompanied by the interplanetary sector boundary crossing early on January 31. The interplanetary magnetic field north-south component in the stream interaction region was fluctuating and not very strong (down to -5 nT only). The geomagnetic conditions remained quiet.

SIDC Weekly bulletin on Solar and Geomagnetic activity
WEEK 475 from 2010 Feb 01

SOLAR ACTIVITY

Solar activity was very quiet until Feb. 5th when a new active region appeared at about N25E35. It was labeled AR 1045 the next day by NOAA. It produced 3 M-class flares between Feb. 6th and Feb. 7th, the biggest one peaking at M6.4 on Feb. 7th, 02:34 UT. It was linked to a halo CME observed by the LASCO coronagraphs.

GEOMAGNETIC ACTIVITY

Geomagnetic activity was rather weak during the whole week. There was a brief period of unsettled conditions (k=4), observed at Dourbes observatory, on Feb. 2nd, due to the crossing of a fast solar wind stream by the Earth.

SIDC Weekly bulletin on Solar and Geomagnetic activity
WEEK 476 from 2010 Feb 08

SOLAR ACTIVITY

Several M-flares occurred this week. The source region was NOAA AR 1045/Catania 40. NOAA AR 1046/Catania 41 was responsible for the M8.3 flare of Feb 12.

The M6.4 flare of Feb 07, peaking at 02:34UT was associated with a plasma eruption which was Earth directed. The active region 1045 was at that moment located near the central meridian. The projected speed of the CME was calculated to be 339 km/s by CACTus, a software to automatically detect CMEs in LASCO images. On Feb 13, at the position N30E30, a coronal dimming and a running wave front in a series of EIT-images are visible. The event started at 12:36T. The dimming and the EIT wave are on-disk signatures of the ejection of a plasma cloud. CACTus detected a very small cloud at 14:06UT. The only flaring activity, a C9.5 flare, at that moment came from an active region at that moment behind the east limb. The flare and the coronal dimming/EIT-wave are probably not associated. However, CACTus spotted a partial halo CME with an projected speed of 306 km/s at 19:54UT.

GEOMAGNETIC ACTIVITY

Geomagnetic activity was low this week.

ACE data show the arrival of two magnetic structures. Early Feb 11, a jump in the magnetic field strength occurred. This structure is possibly linked with the CME associated with the M6.4 flare of Feb 07. The geomagnetic response was minor: Kp became 2.

On Feb 15, another magnetic structure arrived. This can be redrawn to the partial halo CME seen on Feb 13. The Kp went up to 4 late Feb 15-early Feb 16.
